\emergencystretch [$\langle dimen \rangle$ parameter]

By setting this parameter to be greater than zero, you can make it easier for TEX to typeset your document without generating overfull hboxes. This is a better alternative than setting \tolerance=10000, since that tends to produce really ugly lines. If TEX can't typeset a paragraph without exceeding \tolerance, it will try again, adding \emergencystretch to the stretch of each line. The effect of the change is to scale down the badness of each line, enabling TEX to make spaces wider than they would otherwise be and thus choose line breaks that are as good as possible under the circumstances.
