\insert $\langle number \rangle$ { $\langle vertical \ mode \ material \rangle$ }

This primitive command provides the underlying mechanism for constructing insertions, but it is hardly ever used outside of a macro definition. The definitions of the \footnote, \vfootnote, \topinsert, \midinsert, and \pageinsert commands are all built around \insert.

When you design insertions for a document, you should assign a different integer $code^1$ n to each kind of insertion, using the \newinsert command (p. '\@newinsert') to obtain the integer codes. The \insert command itself appends the \(\lambda\text{vertical mode material}\rangle\) to the current horizontal or vertical list. Your output routine is responsible for moving the inserted material from where it resides in \box n to an output page.

 $T_{E}X$ groups together all insertions having the same code number. Each insertion code n has four registers associated with it:

- \box n is where T_EX accumulates the material for insertions with code n. When T_EX breaks a page, it puts into $\box n$ as much insertion n material as will fit on the page. Your output routine should then move this material to the actual page. You can use $\begin{align*} \begin{align*} \beg$
- \count n is a magnification factor f. When TEX is computing the vertical space occupied on the page by insertion n material, it multiplies the vertical extent of this material by f/1000. Thus you would ordinarily set f to 500 for a double-column insertion and to 0 for a marginal note.
- \d imen n specifies the maximum amount of insertion n material that TFX will put on a single page.
- \skip n specifies extra space that TeX allocates on the page if the page contains any insertion n material. This space is in addition to the space occupied by the insertion itself. For example, it would account for the space on a page above the footnotes (if there are any).

TEX sets $\box n$, and you should set the other three registers so that TEX can correctly compute the vertical space required by the insertion. See pages 122–125 of The TEXbook for further details of how TEX processes this command and of how insertions interact with page breaking.

¹ The TeXbook uses the term "class" for a code. We use a different term to avoid confusion with the other meaning of "class" (p. 'class').
